

Braking wind effect in power plants

Overview

Aerodynamic braking is a method used to regulate the speed of wind turbines by manipulating the impact of the wind on the turbine blades. This article discusses wind turbine power control systems, control systems and braking systems, since each type of these systems has its own specific and narrowly. Abstract: This paper focuses on the importance of wind turbine braking systems and their role in controlling and stopping the rotor during maintenance, emergencies, and extreme weather conditions. It highlights the significance of safe and controlled shutdowns in preventing excessive wear and tear. As power systems integrate higher shares of wind and solar, assessing their impact on system dynamics becomes increasingly important. Wind turbine brakes will improve maintenance, manage risks, and protect costs. To ensure their safe operation, longevity, and efficiency, a robust and reliable braking system is not just a component—it's a critical safety necessity.
