

Seasonal differences in wind power generation

Overview

Seasonal variations can significantly impact wind energy production. In winter, increased storm activity and higher wind speeds often result in greater energy output, whereas, in summer, calmer weather patterns may reduce production capabilities. Wind patterns are influenced by the Earth's rotation, the distribution of land and water, and seasonal variations. During winter, wind. Note: Data include facilities with a net summer capacity of 1 MW and above only. Wind plant generation performance varies throughout the year as a result of highly seasonal wind patterns. Nationally, wind plant performance tends to be highest during the spring and lowest during the mid- to late. The power generation figures of using a mean and a dynamic air density value were compared and the results show that power generation estimates may be under- and overestimated by on average 5% up to 10% in winter and summer, respectively.
